Enabling Delta Life

## Adaptive Water Management in the Netherlands

Marcel Marchand  
Deltares

Adelaide, 25 June 2012

## The Netherlands: a delta with international rivers

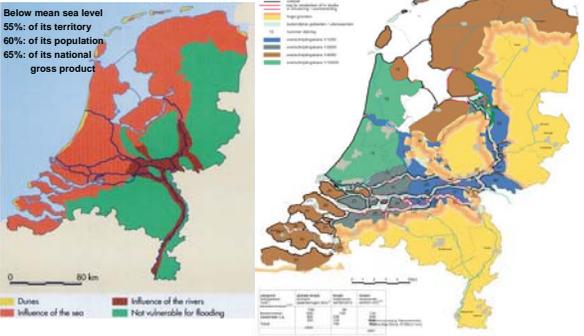

Legend:  
 Rhine  
 Meuse  
 Scheldt  
 EMS

Map labels: THE NETHERLANDS, BELGIUM, GERMANY, FRANCE, SWITZERLAND

**Deltares**

## Flood control in the Netherlands

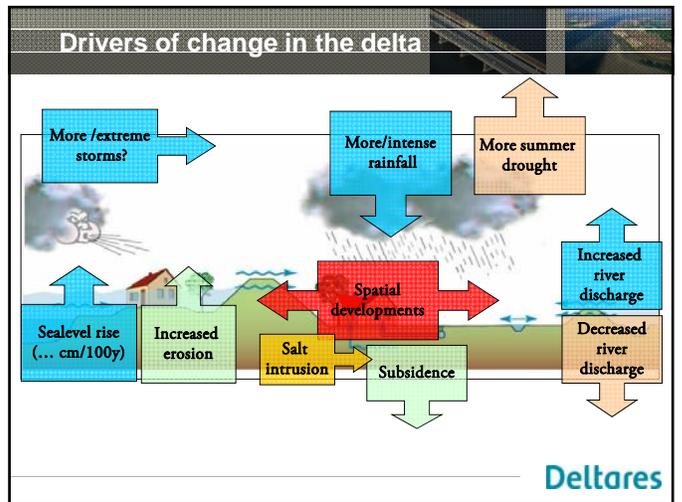

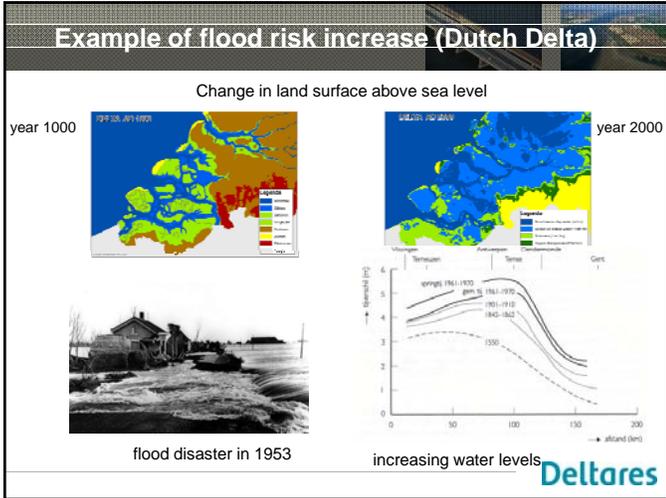

**Below mean sea level**  
 55% of its territory  
 90% of its population  
 65% of its national gross product

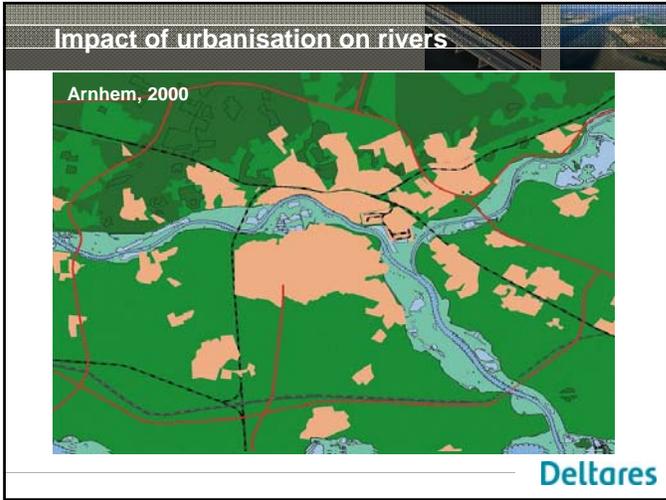

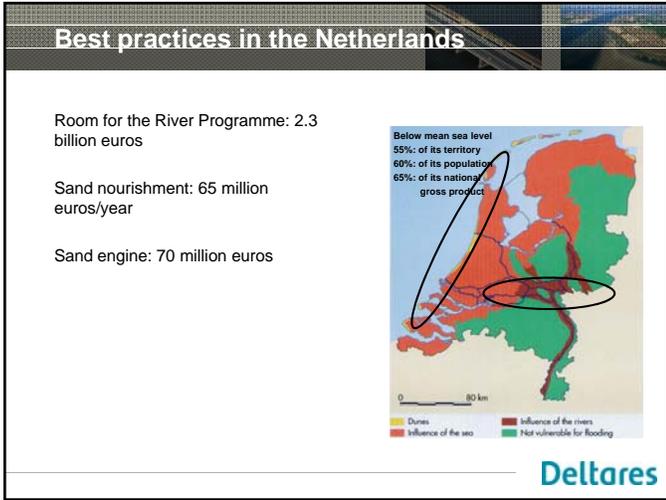

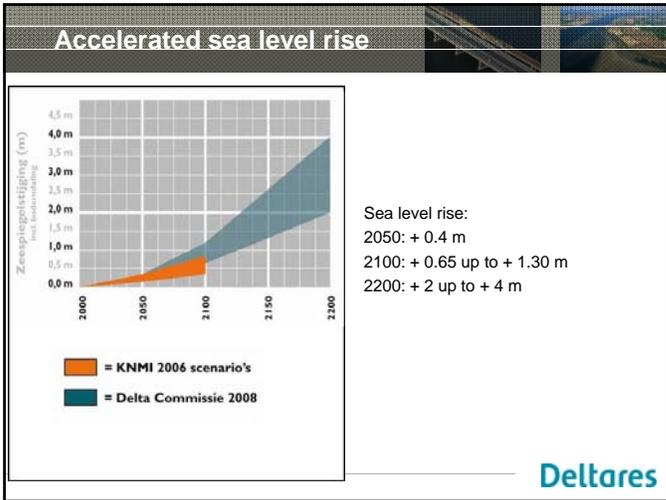

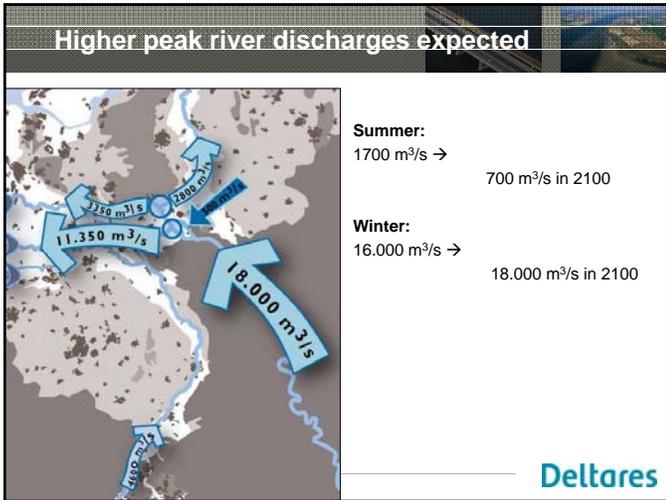

Legend:  
 Dunes  
 Influence of the sea  
 Influence of the rivers  
 Not vulnerable for flooding

**Deltares**

## Age old struggle against water

## Best practices: Room for the River

### Objectives:

- Safety: accommodate 16.000 m<sup>3</sup>/s without flooding
- Enhance nature, landscape amenity, transport over water

Selection of 700 local measures (consisting of 8 measure types);  
Planning Kit (DSS) prepared by scientists, used by locals

### Best practices: Sand nourishment / sand engine

Objectives:

1. Guarantee safety from flooding (dune strength)
2. Maintain coastline position of 1990
3. Preserve coastal foundation

Measure: various types of sand nourishment

### Coastline management in 3 scale levels

Days / metres

Years / km

Century / 10-100 km

**Deltares**

### Sand Engine: mega-nourishment for 20 years

Sand redistribution by nature itself

- Less disturbance of sea floor from dredging
- Recreational space
- Nature development

**Deltares**

### Some theoretical background

Simple Delta model:      Applied to flood risk management:

Drivers of change: Population growth, Economic development; Technology, innovations; Climate change, subsidence

Delta Layers: Occupation (Land and water use); Infrastructure; Physical base (Air, water and soil)

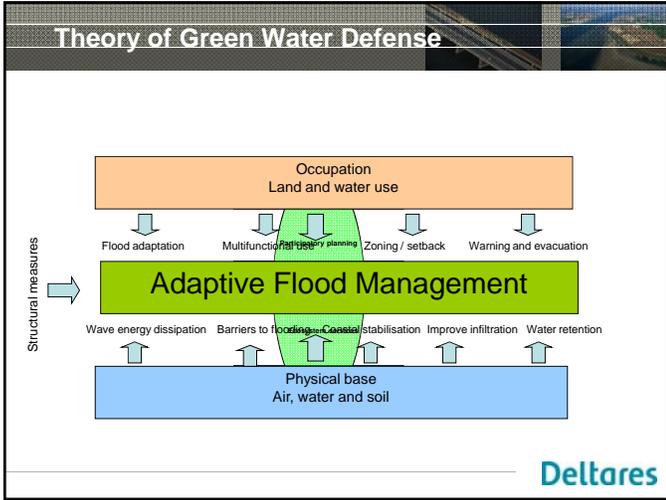

Flood Risk Management: Flood vulnerability; Flood exposure; Flood protection; Flood hazard

Flood Risk

Flood risk = Hazard x Vulnerability x Protection

Changes in flood risk =  $\Sigma$ (climate change, subsidence, pop.growth, econ. development)

**Deltares**

### The Hazards

- Coastal floods**
  - Storm surges and typhoons
  - Tidal waves
  - Tsunamis
- Fluvial floods**
  - Mainstream
  - Flash floods
- Pluvial floods**
  - Heavy rainfall
  - Bad performance of drainage system

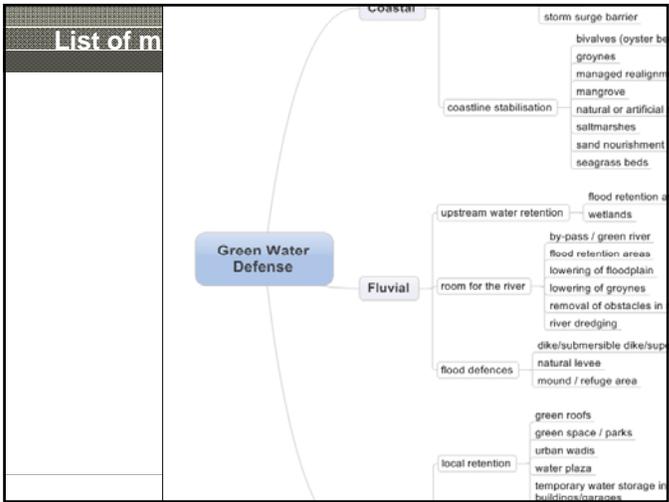

Tsunamis are often no taller than normal wind waves, but they are much more dangerous.

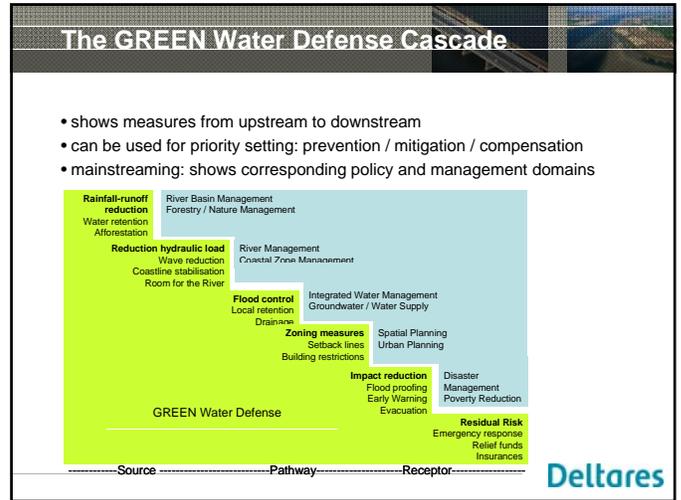

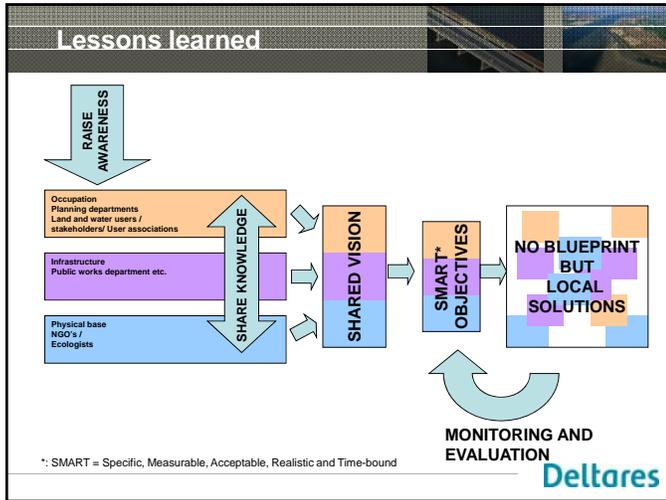

Wind waves come and go without flooding higher areas.

Tsunamis run quickly over the land as a wall of water.

### Non-structural measures (planning etc.)

- Flood adaptation
- Zoning and coastal setback lines
- Multifunctional use of infrastructure
- Warning and evacuation

### Conclusions Adaptive Flood Management...

- is **feasible and effective**, can be **cheaper** than traditional solutions, and is often more **cost-efficient** because it serves multiple purposes
- is a **paradigm shift** (soft versus hard engineering), requires flexibility in thought
- is more **adaptive**, but has also more uncertainty in end result (non-linearity in ecosystem services)
- is **soft** when possible, **hard** when required
- makes use of the **genius of the place**: best practices are not easily transplanted, requires tailor made approach

Deltares

### Recommendations

- Use the GREEN Water Cascade for mainstreaming with other policy and management domains.
- Start a dialogue between: planning departments, land and water users in the occupation layer, public works and other infrastructure departments in the network layer and environmental departments, ecologists and NGO's in the base layer.
- Build a knowledge base and communities of practice – both internationally and locally – to promote a better flow of knowledge.
- Develop guiding principles, promote education and training and organise design workshops.
- Implement pilot projects as experiment sites to gain further knowledge and to learn from the field.
